Install Ollama & Pull Your First Model

RDAT Copilot uses **Ollama** as its primary local LLM engine. Ollama runs entirely on your machine — no data leaves your device.

1 Download & install Ollama

Visit ollama.com/download and download the installer for your platform. Run the installer — on Windows and macOS, Ollama starts automatically. On Linux, run `ollama serve` in a terminal.

2 Launch RDAT Copilot

Open the RDAT Copilot desktop app. On first run, an onboarding modal will appear to verify Ollama is running. Click **Check now** — if successful, the modal dismisses automatically. If you skip it, the app runs in degraded LTE-only mode.

3 Pull Gemma 4 E2B (recommended starter)

Open the **Models** panel. Click **Pull** on `gemma4:e2b`. The ~1.5 GB download takes 2–10 minutes. Larger alternatives: `gemma4:e4b` (~3 GB) or `qwen3:4b` (~2.5 GB).

4 Load the model

After the pull completes, click **Load** on the same card. The status banner turns green and shows **Active model: `gemma4:e2b`**. The model stays loaded for 5 minutes of inactivity (Ollama's default keep-alive).

Tip: If you skip Ollama installation, the app still works — but only the LTE (corpus match) tier will produce suggestions. To enable the local LLM tier, install Ollama and load a model.

Translate with Ghost-Text Suggestions

Click **Launch Editor** from the dashboard. Paste English source text in the left panel — it's auto-segmented into sentences. Click any segment to start translating. As you type Arabic, ghost-text suggestions appear inline with a colored badge showing the source tier.

BADGE	SOURCE	LATENCY
LTE	Local Translation Engine — instant corpus match (~80 seed pairs + your glossary)	< 5 ms
GEMMA4	Local LLM via Ollama — RAG-augmented, glossary-aware (PRIMARY ENGINE)	200–2000 ms
GEMINI	Cloud fallback via Gemini 2.5 Flash (optional, requires API key)	500–3000 ms

Tab	Ctrl + →	Alt +]	Ctrl + ↵
Accept full suggestion	Accept next word	Cycle candidates	Confirm segment

Optional Gemini fallback: Add your key in **API Keys** panel from aistudio.google.com/apikey. Stored locally; sent via Rust backend only.
